COMPUTE PRICE

Methodology

PRICE SNAPSHOT
13 Nov 2026 · 19:55 UTC

We estimate hourly cloud rental costs from **2,025 CPU configurations** and **82 GPU configurations** from AWS, Microsoft Azure and Google Cloud. These are the samples shown in the Data tab. Prices are public Linux on-demand rates for one US region per provider, excluding discounts, taxes and separately billed storage or traffic.

THE TWO PRICE EQUATIONS

$$\text{CPU:}\quad H = 0.25888\,(R/16)^{0.71840}\,(C/5000)^{0.44859}$$

$$\text{GPU:}\quad P = H + 0.00171247\,nB$$

H: CPU/RAM cost. **P**: full GPU-machine cost. Both are in USD/hour.
R: RAM (GiB). **C**: whole-machine Geekbench 6 multi-core score.
n: number of GPUs. **B**: memory bandwidth per GPU (GB/s).

How we fit and check the models

First, we fit CPU prices using RAM and measured CPU performance. Then we add a GPU cost proportional to memory bandwidth. We fit log prices to focus on relative errors; GPU machine families receive equal weight. VRAM is omitted because it closely tracks bandwidth in this sample.

To check predictions, we leave related machine sizes out together, fit without that family, and predict its prices. The fit plots show these predictions against listed prices. Average absolute percentage errors are **27.5% for CPU** and **22.3% for GPU**.

Reference prices and history

The CPU reference uses the base Mac mini M6: 16 GB RAM and a 20,525 Geekbench 6 score. The GPU reference adds one H100 SXM at 3,350 GB/s. This is a hypothetical resource basket. The Mac score is a performance proxy; H100 bandwidth exceeds the fitted sample, so its price estimate extends beyond the observed range.

The history chart refits the same equations to archived AWS prices, using later benchmarks of matching VM shapes. It estimates the cost of the fixed reference over time; it does not represent historical Mac mini or H100 rental offers.

Daily updates and limits

Each day, we refresh prices, refit the models and regenerate this document; benchmarks stay fixed. Incomplete updates retain the dated snapshot. Missing inputs, unverified units and prices older than 36 hours are excluded from new fits. These are approximate estimates, not provider quotes or guarantees of application performance.
